

(International Fight Against Stealth Virus)

New coronavirus (COVID-19) born from China has begun to fly on five continents.

Worldwide isolation is being implemented. However, by the early experiences in Japan, Korea and the other countries, the virus has been proven to be unprotected by quarantine. The reason is clear that a subclinical person affected with the virus can sprinkle the virus to the other people. Even you might be such a person. The virus can slip through quarantine. How can you detect such a person? The mission is impossible. The virus is “STEALTH VIRUS”. Such a person can be called by “STEALTH PATIENTS”.

In other words, the pandemic cannot be prevented by a classic quarantine strategy. So, within several months, the world may have several billion of “STEALTH PATIENTS”.

The main target of the virus is known to be health minority population (the elders, patients of the other diseases). The “STEALTH VIRUS” of some billions of “STEALTH PATIENTS” can destroy them around the world.

Quarantine is already not effective. Only drug and vaccines.

World countries should raise new international funds to accelerate the urgent research development of the drugs and vaccine.
